

EWA ŁUCZKOWSKA¹

**INAEQUALINA N. GEN. (FORAMINIFERIDA, MILIOLINA)
AND ITS STRATIGRAPHIC DISTRIBUTION**

(Pl. XXVIII)

*Nowy rodzaj Inaequalina (Foraminiferida, Miliolina) i jego zasięg
stratygraficzny
(Tabl. XXVIII)*

A b s t r a c t: A new genus *Inaequalina* in the Badenian (Tortonian) sediments of Poland is distinguished. The genus is related to *Ophthalmidium* in having similar character of the aperture and at the same time related to *Spiroloculina* in having similar chamber arrangement. It differs from both two in the plano-convex test with chambers arrangement in two planes of coiling 140—170° apart.

INTRODUCTION

Several specimens of porcellaneous Foraminifera, resembling *Spiroloculina*, but with unequal tests flattened on one side and raised on the other one were found in the Lower Badenian (Tortonian) sediments of Poland. Possibly they were attached to the bottom by the flattened part of the test. Similar specimens were described from the Pliocene and Recent sediments by Schluemberger, Terquem, Brady and Cushman as:

- | |
|---|
| <i>Spiroloculina advena</i> Cushman, 1921, Recent |
| „ <i>inaequilateralis</i> Schluemberger, 1893, Recent |
| „ <i>affixa</i> Terquem, 1878, Pliocene |
| „ <i>disparilis</i> Terquem, 1878, Pliocene |
| „ <i>acutimargo</i> Brady, 1884, Recent |
| „ <i>tenuimargo</i> Cushman, 1917, Recent |

The species mentioned above, except for the last two, show common features: unequal tests, not planispirally coiled, aperture at the extend, flattened end of the last chamber, lacking tooth (except for *S. disparilis* which has a simple tooth) and a spiroloculine arrangement of chambers. The two last species show flattened, planispirally coiled tests, but apertures without tooth, like specimens described below. The before last, *S. acutimargo*, has loosely coiled chambers arrangement and is classified as *Ophthalmidium*, whereas the last one, *S. tenuimargo*, differs from *S. acutimargo* by having chambers closely adjacent one to another, not separated by flat plate-like portions of previous convolutions, as it is in *Spiroculina* and in our specimens.

¹ Kraków, al. Mickiewicza 30, Instytut Geologii Regionalnej i Złoże Węgli, Zakład Paleontologii i Stratygrafii AGH.

It is beyond of the author's intention to discuss further if *S. acutimargo* was justly included to the genus *Ophthalmidium*, which is probably confined to the Jurassic sediments only, and if *S. tenuimargo* has really planispirally coiled chambers. The author observed in Recent materials from Indian Ocean specimens similar to *S. tenuimargo*, but with one distinctly flattened side of the test. Before the problem of these two species will be studied, the species with unequal tests, not planispirally coiled, and with small elongate apertures without tooth would be considered as belonging to a new genus *Inaequalina*, closely related to the genus *Ophthalmidium* in having the same character of the aperture and at the same time related to the genus *Spiroloculina* in having similar chamber arrangement.

STRATIGRAPHIC DISTRIBUTION

The genus *Inaequalina* appears in Miocene sediments of Paratethys, is known from Pliocene and Recent sediments of the Mediterranean and probably from Recent sediments of the Atlantic and the Pacific.

SYSTEMATIC DESCRIPTION

Class: Rhizopoda
Order: Foraminiferida
Suborder: Miliolina
Superfamily: Miliolacea
Family: Nubeculariidae
Subfamily: Ophthalmidiinae

Inaequalina gen. n.

Type species: *Spiroloculina inaequilateralis* Schumberger, 1893.

Type reference: Schumberger, C., Monographie des Miliolidées du golfe de Marseille. Soc. Zool. France, Mém., Paris, France, 1893, tome 6, p. 60, tf. 3, pl. 4, figs. 84—86.

Name derivation: from the Latin word *inaequalis* = unequal, uneven.

Diagnosis: Chambers arranged as in *Spiroloculina*, but in two planes of coiling 140—170° apart, aperture slitlike to rectangular, without tooth.

Description: Test more or less planoconvex, ovate to fusiform in outline, consisting of ovate proloculus followed by spirally wound second chamber of complete whorl in length, enlarging toward the apertural end, later chambers one-half coil in length, being regularly added on alternate sides in two planes of coiling 140—170° apart, so that one side of the test is flattened and the opposite side is more or less raised; all chambers, except proloculus, quadrangular in section and closely adjacent one to another, not separated, each of them equipped with apertural enlarging as those of *Ophthalmidium*; proloculus visible on both sides of the test; wall calcareous, porcelaneous, imperforate; aperture at the extend, flattened end of final chamber, slit-like to rectangular, without tooth.

Remarks: It differs from *Ophthalmidium* and *Spirophthalmidium* in the planoconvex test, in the stability and symmetry in the arrangement of chambers, and in lacking loosely coiled chambers and flattened plates

between whorls; the ovate proloculus is encircled by a second chamber of complete whorl in length (as in *Spiroloculina*), quadrangular in section and enlarging to the end, whereas *Ophthalmidium* has the spherical or slightly elliptical proloculus, the second chamber one half to one whorl in length, the third one of the complete whorl and only the next chambers gradually reduced in length to half a turn or longer than half a turn; from *Spiroloculina* it differs in the planoconvex test and the slit-like aperture without tooth.

Occurrence: Miocene — Recent, cosmopolitan.

Inaequalina jadwigae sp. n.
(Pl. XXVIII figs. 1—11)

Holotype: Pl. I fig. 1 a—c.

Type level: Miocene, Lower Badenian (Tortonian).

Type locality: Korytnica near Jędrzejów, outcrop.

Type specimen: Holotype Nr. F-V/185 stored in the Department of Paleontology and Stratigraphy of the Academy of Mining and Metallurgy in Cracow, Poland.

Name derivation: from the first name of author's daughter.

Material: 26 specimens well preserved.

Dimensions:

	breadth mm	height mm
Holotype	0,67	1,35
Paratypes	0,17—0,72	0,31—1,25

Diagnosis: Test slender, ovate in outline, tapering to the both ends; proloculus ovate; the second chamber primarily tubular, beginning from 1/3 of length quadrangular in section, encircling the proloculus; later chambers regularly added on both sides of the long axis of the test; each chamber with two sharp keels: one on the edge and the other one along the middle of the chamber wall on the raised side; chamber walls primarily flattened and concave in the adult.

Description: Test planoconvex, ovate in outline, tapering slightly to the both ends, the apertural end flattened and extend, periphery sharply keeled; on the flat side of the test all chambers visible, increasing rapidly in size, with a well visible ovate proloculus raised a little up and the second chamber encircling the proloculus; the second chamber primarily tubular, from 1/3 of length enlarging and becoming quadrangular in section; later chambers regularly added on both sides of the long axis of the test, not tapering to the end; sutures flat, with a thickened keel of the previous chamber visible along each suture; on the convex side the same chambers are visible, but each one with a raised keel along the middle of the chamber; sutures flat, defined only by raised carines of previous chambers; chamber walls flat in the young stage and concave in the adult; all chambers adjacent very loosely one to another and get easily separated whereas only the proloculus with the second chamber stick together; surface smooth; wall structure cryptocrystalline, homogeneous, without exact crystal orientation in the middle layer of the wall observed in the thin-section, but with a certain orientation of tiny crystals perpendicular to the surface at the outer and inner margin of the wall; wall colour brownish in transmitted light; aperture slit-like, without tooth, at the extend, flattened end of the last chamber.

D i m o r p h i s m: With the studied specimens only megalospheric forms were observed. The dimensions of proloculus: breadth — 0,02—0,04, height — 0,05—0,08 mm.

V a r i a b i l i t y: The variability of the shape of the test is observed, being slender and less carinate in young stage and becoming broader and sharply carinate in the adult.

R e m a r k s: It differs from *Spiroloculina advena* C u s h m a n and *Spiroloculina inaequilateralis* S c h l ü m b e r g e r in its more slender shape with tapering ends and sharply keeled chambers with concave walls in the adult. From *Spiroloculina affixa* T e r q u e m it differs in having all chambers regularly added as well as in the concave wall chambers and the presence of sharply keels. From *Spiroloculina disparsilis* T e r q u e m it differs in lacking the simple tooth in the aperture and in more ovate shape of the test. It shows a great similarity to *Spiroloculina acutimargo* B r a d y, but differs in having a planoconvex test and in lacking separation of chambers by the intervening wing of the previous convolution and a tubular extension with small aperture on the final chamber. From *Spiroloculina tenuimargo* C u s h m a n it differs in lacking the compressed test and a round aperture.

STRESZCZENIE

W osadach dolnego badenianu (tortonu s.l.) na obszarze Polski znaleziono okazy otwornic o „porcelanowych” skorupkach, przypominające *Spiroloculina*, lecz o niesymetrycznym, płasko-wypukłym układzie komór. Podobne okazy były opisywane przez S c h l ü m b e r g e r a, T e r q u e m a, B r a d y'ego i C u s h m a n a z pliocenu i osadów współczesnych M o rza Śródziemnego, Atlantyku i Pacyfiku. Budowa ich wykazuje pokrewieństwo z rodzajem *Ophthalmidium* ze względu na szparowane ujście

bez zęba, oraz z rodzajem *Spiroloculina* ze względu na podobny układ komór. Od obu tych rodzajów różnią się jednak ułożeniem komór w dwu płaszczyznach zwojowych pod kątem 140—170°; poza tym od rodzaju *Ophthalmidium* różnią się budową części embrionalnej oraz brakiem luźno zwiniętych komór i płytka międzykomorowych, a od rodzaju *Spiroloculina* odmiennym ujściem bez zęba. Ich zasięg stratygraficzny obejmuje osady miocenu Paratetydy, pliocenu i osadów współczesnych Morza Śródziemnego oraz prawdopodobnie osadów współczesnych Atlantyku i Pacyfiku.
